Abstract

In this article, we are interested in the behaviour of a single ferromagnetic mono-domain particle submitted to an external field with a stochastic perturbation. This model is the first step toward the mathematical understanding of thermal effects on a ferromagnet. In a first part, we present the stochastic model and prove that the associated stochastic differential equation is well defined. The second part is dedicated to the study of the long time behaviour of the magnetic moment and in the third part we prove that the stochastic perturbation induces a non reversibility phenomenon. Last, we illustrate these results through numerical simulations of our stochastic model. The main results presented in this article are on the one hand the rate of convergence of the magnetization toward the unique stable equilibrium of the deterministic model and on the other hand a sharp estimate of the hysteresis phenomenon induced by the stochastic perturbation (remember that with no perturbation, the magnetic moment remains constant).

Keywords: convergence rate, stochastic dynamical systems, long time study, magnetism, hysteresis.

AMS Classification: 60F10, 60F15, 65Z05

1 Introduction

Thermal effects in ferromagnetic materials are essential in order to understand their behaviour at ambient temperature or, more critically, in electronic devices where the Joule effect induces high heat fluxes. This effect is commonly modeled by the introduction of a noise at microscopic scale on the magnetic moment direction and at the mesoscopic scale by a transition of behaviour. In ferromagnetic materials, the transition between the non-linear behaviour and the linear behaviour is managed by the struggle between the Heisenberg interaction and the disorder induced by the heating. This model explains the critical temperatures such as the Curie temperature for ferromagnetic materials. In this context, it is essential to understand the impact of introducing stochastic perturbations in deterministic

models of ferromagnetic materials such as the micromagnetism (see Brown (1962, 1963)).

The understanding of this phenomena is a key point in order to simulate realistic ferromagnetic devices such as micro electronic circuits. Furthermore, heating has a real effect on the microstructure dynamics in magnets; then, efficiently controlled, the dynamics of microstructures could accelerate processes such as the magnetization switching, which is the basics of magnetic recording techniques.

During the last decade, several studies have been initialized in several articles by physicists (e.g. Mercer et al. (2011); Zheng et al. (2003); Raikher et al. (2004); Atkinson et al. (2003); Raikher and Stepanov (2007); Scholz et al. (2001); Martinez et al. (2007); Smith (2001)), but to our knowledge very few if no mathematical models justifying this kind of effects at the micro-scale have been developed for continuous state magnetic spins. Numerous studies focused on the discrete state spin approach (in particular the Glauber dynamic model, see for instance Bovier et al. (2010)), but in our context, we try to catch the magnetization defects induced by thermal effects in ferromagnetic materials seen from the dynamical point of view of the Larmor precession equation. In this article, our goal is to improve the understanding of thermal effects in ferromagnets. To achieve this goal, we focus this first study on the dynamic of a single magnetic moment submitted to a stochastic perturbation. Our main aim is to characterize precisely the dynamic of the moment, giving estimates and general behaviour in long time. In particular, we will exhibit an hysteresis behaviour of the magnetization in our model.

The model we are studying mimics the behaviour of a single magnetic moment $\mu(t)$ (function from \mathbb{R} into $S(\mathbb{R}^3) = \{u \in \mathbb{R}^3; |\mu| = 1\}$) submitted to an external field b . The dynamic of such a system is, at the micro-scale, described by the Larmor precession equation

$$\frac{d\mu}{dt} = -\mu \wedge b.$$

Nevertheless, this equation is non dissipative and, in order to make the theoretical study easier, we introduce a dissipative part using the Landau-Lifchitz equation

$$\frac{d\mu}{dt} = -\mu \wedge b - \alpha \mu \wedge (\mu \wedge b),$$

where α is a positive real constant and we set the initial condition $\mu(0) = \mu_0 \in S(\mathbb{R}^3)$. We point out two major properties of this system

- i. $\forall t \in \mathbb{R}, |\mu(t)| = 1,$
- ii. $\forall t \in \mathbb{R}, \frac{d}{dt}(\mu(t) \cdot b) \geq 0.$

The first property, which is definitely essential, will have to be preserved by the stochastic system and the second property is the energy decreasing induced by the introduction of the dissipation term. The dynamic of this deterministic system is classical; in fact, one knows that $\lim_{t \rightarrow \infty} \mu(t) = \frac{1}{|b|}b$ provided that $\mu(0) \neq -b$. In this work, we will develop such a result for the stochastic system. In order to build this stochastic system, the first question is how to introduce the stochastic perturbation in the deterministic system. We want to model

the thermal effects which are external perturbations of the magnetic moment. In fact, this perturbation could be modeled has an external perturbation field. In the sequel, we will choose to build a stochastic system by perturbing the external field with a Brownian motion. We will write down

$$\begin{cases} dY_t &= -\mu_t \wedge (b \, dt + \varepsilon \, dW_t) - \alpha \mu_t \wedge (\mu_t \wedge (b \, dt + \varepsilon \, dW_t)) \\ Y_0 &= y \in \mathcal{S}(\mathbb{R}^3). \end{cases}$$

where ε is a strictly positive real number and W a standard Brownian motion with values in \mathbb{R}^3 . But, an easy computation of $d(|Y_t|^2)$ using Itô's formula shows that the process Y will not stay in $\mathcal{S}(\mathbb{R}^3)$, then, in order to preserve this essential behaviour, we have to renormalise the previous equation and set

$$\mu_t = \frac{Y_t}{|Y_t|}.$$

Given this system, we prove the following results

i. $\mu_t \cdot b \xrightarrow[t \rightarrow \infty]{} |b|$, a.s.,

ii. $\lim_{t \rightarrow \infty} \sqrt{t} \, \mathbb{E}[|b| - \mu_t \cdot b]$ exists and we can compute its value.

Note that these results are only valid for $\alpha > 0$, as for $\alpha = 0$, it is easy to show that the function $e(t) = \mathbb{E}(\mu_t \cdot b)$ satisfies the following ordinary differential equation $e'(t) = -e(t) \frac{h'(t)}{h(t)}$.

Hence, $e(t) = \frac{e(0)}{h(t)} \xrightarrow[t \rightarrow \infty]{} 0$. This contradicts the a.s. convergence of μ_t to $\frac{b}{|b|}$.

iii. When μ is submitted to a time varying external field, an hysteresis phenomenon appears. If we consider $\mathbf{b} \in \mathcal{S}(\mathbb{R}^3)$ and let b linearly vary between $+\mathbf{b}$ and $-\mathbf{b}$ over the time interval $[0, T]$, then $\mathbb{E}(\mu_t \cdot \mathbf{b})$ is bounded from below by $\frac{1}{\sqrt{1+ct}}$ for $t \leq T/2$ where c is a constant depending only on ε and α .

First, we make precise the derivation of the stochastic model and discuss the physical differences between the Itô interpretation or the Stratonovich one of the noise term. Then, we lead a detailed study of its asymptotic behaviour and in particular we point out an hysteresis phenomenon. This phenomenon is obtained by slow variations of the external field such that the dynamic of relaxation of the magnetization toward this field becomes instantaneous when the speed ratio of the external excitation goes to zero. The results shown in this article are finally illustrated by numerical simulations.

Notations:

- For a and b in \mathbb{R}^3 we denote by $a \cdot b$ their scalar product, $a \cdot b = \sum_{i=1}^3 a^i b^i$.
- For a in \mathbb{R}^3 , we denote by $|a| = \sqrt{a \cdot a}$ the Euclidean norm of a .
- We like to encode elements of \mathbb{R}^3 as column vectors. For $x \in \mathbb{R}^3$, x^* is a row vector. Similarly, we use the star notation “*” to denote the transpose of matrices.
- If $H = (H_t)_{t \geq 0}$ is a 3-dimensional \mathbb{F} -adapted process satisfying $\int_0^t |H_u|^2 du < \infty$ a.s. for all t , we may write $\int_0^t H_u \cdot dW_u$ for $\sum_{i=1}^3 \int_0^t H_u^i dW_u^i$ and use the differential form $H_t \cdot dW_t$ for $\sum_{i=1}^3 H_t^i dW_t^i$.

2 Mathematical model

2.1 First properties of the model

Let $(\Omega, \mathcal{A}, \mathbb{P})$ be a probability space. We consider a standard Brownian motion W defined on this space with values in \mathbb{R}^3 and denote by $\mathbb{F} = (\mathcal{F}_t)_{t \geq 0}$ its natural filtration augmented with \mathbb{P} -null sets.

Let $b \in \mathbb{R}^3$ be the magnetic field. We model the $\mathcal{S}(\mathbb{R}^3)$ -valued magnetic moment process $\mu = (\mu_t)_{t \geq 0}$ by the following coupled stochastic differential equation (SDE in short)

$$\begin{cases} dY_t &= -\mu_t \wedge (b \, dt + \varepsilon \, dW_t) - \alpha \mu_t \wedge (\mu_t \wedge (b \, dt + \varepsilon \, dW_t)) \\ \mu_t &= \frac{Y_t}{|Y_t|} \\ Y_0 &= y \in \mathcal{S}(\mathbb{R}^3), \end{cases} \quad (2.1)$$

where $\alpha > 0$ is the magnitude of the damping term and $\varepsilon > 0$ is the magnitude of the noise term.

The term $\mu_t \wedge dW_t$ in (2.1) is naturally defined by introducing the antisymmetric operator $L : \mathbb{R}^3 \mapsto \mathbb{R}^{3 \times 3}$ associated to the vector product in \mathbb{R}^3

$$L(x) = \begin{pmatrix} 0 & -x^3 & x^2 \\ x^3 & 0 & -x^1 \\ -x^2 & x^1 & 0 \end{pmatrix}.$$

Hence, for a 3-dimensional \mathbb{F} -adapted process H satisfying $\int_0^t |H_s|^2 \, ds < \infty$ a.s. for all $t > 0$, the process $\int_0^t H_s \wedge dW_s$ is defined by $\int_0^t L(H_s) dW_s$, which is a standard multi-dimensional Itô stochastic integral. When dealing with the differential expression, we will either write $H_t \wedge dW_t$ or $L(H_t) dW_t$.

Proposition 1. *Let (Y, μ) be a pair of processes satisfying (2.1), then*

$$d|Y_t|^2 = 2\varepsilon^2(\alpha^2 + 1)dt$$

and therefore $|Y_t| = \sqrt{2\varepsilon^2(\alpha^2 + 1)t + 1}$ is non random.

Remark 2. *The fact that $|Y_t|$ is non random is definitely essential in all the following computations. In particular, we deduce from this result that $|Y_t|$ has finite variation.*

Proof. Using Itô's lemma we have

$$d|Y_t|^2 = 2Y_t \cdot dY_t + \sum_{i=1}^3 d\langle Y^i, Y^i \rangle_t = \sum_{i=1}^3 d\langle Y^i, Y^i \rangle_t,$$

where we have used the fact that Y_t and dY_t are orthogonal. But, using the identity $a \wedge (b \wedge c) = (a \cdot c)b - (a \cdot b)c$, we have

$$\begin{aligned} dY_t &= \varepsilon [-(\mu_t \wedge dW_t) - \alpha((\mu_t \cdot dW_t)\mu_t - (\mu_t \cdot \mu_t)dW_t)] + \dots dt \\ &= \varepsilon A(\mu_t) dW_t + \dots dt, \end{aligned}$$

where we have set $A(\mu) = \alpha I - \alpha(\mu\mu^*) - L(\mu)$ and used $|\mu_t| = 1$. Thus,

$$\begin{aligned} d\langle Y, Y \rangle_t &= \varepsilon^2 AA^*(\mu_t)dt \\ &= \varepsilon^2 \left[\alpha^2 I - \alpha^2(\mu_t\mu_t^*) + \alpha L(\mu_t) - \alpha^2(\mu_t\mu_t^*) + \alpha^2(\mu_t\mu_t^*)(\mu_t\mu_t^*) - \alpha(\mu_t\mu_t^*)L(\mu_t) \right. \\ &\quad \left. - \alpha L(\mu_t) + \alpha L(\mu_t)(\mu_t\mu_t^*) - L(\mu_t)L(\mu_t) \right] dt \\ &= \varepsilon^2 \left[\alpha^2 I - \alpha^2(\mu_t\mu_t^*) + L(\mu_t)L^*(\mu_t) \right] dt, \end{aligned}$$

where we have used $L(\mu)\mu = 0$, $L^*(\mu) = -L(\mu)$ and again $\mu_t^*\mu_t = 1$. Thus, for each $1 \leq i \leq 3$ we have

$$d\langle Y^i, Y^i \rangle_t = \varepsilon^2 \left[\alpha^2 - \alpha^2(\mu_t^i)^2 + \sum_{k=1}^3 (L_{ik}(\mu_t))^2 \right].$$

Then, summing over i , we get

$$\begin{aligned} d|Y_t|^2 &= \varepsilon^2 \left[3\alpha^2 - \alpha^2 |\mu_t|^2 + \sum_{i,j=1}^3 (L_{ij}(\mu_t))^2 \right] dt \\ &= \varepsilon^2 [3\alpha^2 - \alpha^2 |\mu_t|^2 + 2|\mu_t|^2] dt, \end{aligned}$$

The result ensues by remembering that $|\mu_t|^2 = 1$. ■

With the help of Proposition 1, we can establish the SDE satisfied by the one dimensional process $(\mu_t \cdot b)_t$. We introduce the function

$$h(t) = |Y(t)| = \sqrt{2\varepsilon^2(\alpha^2 + 1)t + 1}. \quad (2.2)$$

Since $|Y_t|$ is non random, we deduce from Equation (2.1) that

$$\begin{aligned} d\mu_t &= -\frac{\mu_t h'(t)}{h(t)} dt + \frac{dY_t}{h(t)} \\ &= -\frac{\mu_t h'(t)}{h(t)} dt - \frac{1}{h(t)} (\mu_t \wedge (b dt + \varepsilon dW_t) + \alpha \mu_t \wedge (\mu_t \wedge (b dt + \varepsilon dW_t))) \\ d\mu_t &= -\frac{\mu_t h'(t) + \mu_t \wedge b + \alpha(\mu_t(\mu_t \cdot b) - b)}{h(t)} dt - \frac{\varepsilon}{h(t)} (L(\mu_t) + \alpha(\mu_t\mu_t^* - I)) dW_t \end{aligned} \quad (2.3)$$

By taking the scalar product with b , we get

$$\begin{aligned} d(\mu_t \cdot b) &= -(\mu_t \cdot b) \frac{h'(t)}{h(t)} dt - \frac{\alpha}{h(t)} ((\mu_t \cdot b)^2 - |b|^2) dt \\ &\quad - \frac{\varepsilon}{h(t)} ((\mu_t \wedge dW_t) \cdot b + \alpha(\mu_t \cdot b)(\mu_t \cdot dW_t) - \alpha(b \cdot dW_t)) \\ d(\mu_t \cdot b) &= -(\mu_t \cdot b) \frac{h'(t)}{h(t)} dt - \frac{\alpha}{h(t)} ((\mu_t \cdot b)^2 - |b|^2) dt \\ &\quad - \frac{\varepsilon}{h(t)} (-L(\mu_t)b + \alpha((\mu_t \cdot b)\mu_t - b)) \cdot dW_t \end{aligned} \quad (2.4)$$

We may call this equation the SDE satisfied by $\mu_t \cdot b$ whereas it is not an SDE properly speaking since the r.h.s member actually depends on all the components of μ_t and not only on $\mu_t \cdot b$. Nonetheless, we may use this abuse of terminology throughout the paper.

Remark 3 (Remark on the existence and uniqueness of solutions to Equation (2.1)). *Let us consider the following coupled SDE*

$$dY_t = -\mu_t \wedge (b \, dt + \varepsilon \, dW_t) - \alpha \mu_t \wedge (\mu_t \wedge (b \, dt + \varepsilon \, dW_t)) \quad (2.5a)$$

$$d\mu_t = -\frac{\mu_t h'(t) + \mu_t \wedge b + \alpha(\mu_t(\mu_t \cdot b) - b)}{h(t)} dt - \frac{\varepsilon}{h(t)} (L(\mu_t) + \alpha(\mu_t \mu_t^* - I)) dW_t \quad (2.5b)$$

$$Y_0 = \mu_0 \in \mathcal{S}(\mathbb{R}^3)$$

This system is actually decoupled as the SDE on μ is autonomous (this has only been possible because $|Y_t|$ is non random). The existence and uniqueness of a solution to Equation (2.5) boil down to the ones of Equation (2.5b). By computing $d(|\mu_t|^2)$, we deduce that if there exists a solution μ to Equation (2.5b), $|\mu_t|^2 = 1$ a.s. for all t . Hence, it is sufficient to check the standard global Lipschitz behaviour of the coefficients on $\mathbb{R}_+ \times \mathcal{S}(\mathbb{R}^3)$ to prove existence and uniqueness of a strong solution to Equation (2.5b).

We have already seen above that if a pair (Y, μ) is solution of Equation (2.1), it also solves Equation (2.5).

Conversely, if (Y, μ) is the unique strong solution of Equation (2.5), it is clear that $|Y_t| = h(t)$ by following the proof of Proposition 1 and moreover the computation of $d(Y_t/|Y_t|)$ shows that the process $(Y_t/|Y_t|)_t$ solves the same SDE as μ , hence for all t $\mu_t = \frac{Y_t}{|Y_t|}$ a.s. This last argument proves that Equations (2.1) and (2.5) have the same solutions. Therefore, we deduce that Equation (2.1) admits a unique strong solution denoted by (Y, μ) in the sequel.

2.2 Why we did not choose a Stratonovich rule for the perturbation.

One may argue that if we had written the stochastic perturbation in a Stratonovich way, the norm of the stochastic magnetic moment would have remained constant by construction. This may sound as a favorable argument to go the Stratonovich way but while digging into the two approaches, it eventually becomes clear that the Itô rule and the Stratonovich do not model the same physical phenomenon. This investigation has led us to add a few results on the Stratonovich approach.

The Stratonovich stochastic perturbation. Let ∂ denote the Stratonovich differential operator. In this paragraph, the process $(\bar{\mu}_t)_t$ denotes the stochastic system with a Stratonovich perturbation.

$$\partial \bar{\mu}_t = -\bar{\mu}_t \wedge (b \, \partial t + \varepsilon \, \partial W_t) - \alpha \bar{\mu}_t \wedge \bar{\mu}_t \wedge (b \, \partial t + \varepsilon \, \partial W_t), \quad \bar{\mu}_0 = y \in \mathcal{S}(\mathbb{R}^3). \quad (2.6)$$

The dynamics of $(\bar{\mu}_t)_t$ can be rewritten using the operator $A : \mathbb{R}^3 \rightarrow \mathbb{R}^{3 \times 3}$ defined by $A(x) = \alpha I - \alpha x x^* - L(x)$

$$\partial \bar{\mu}_t = A(\bar{\mu}_t) b \, \partial t + \varepsilon A(\bar{\mu}_t) \partial W_t \quad (2.7)$$

Now, we turn this Stratonovich SDE into an Itô SDE (see (Rogers and Williams, 2000, V.30))

$$d\bar{\mu}_t = A(\bar{\mu}_t) b \, dt + \varepsilon A(\bar{\mu}_t) dW_t + \frac{1}{2} \varepsilon^2 \sum_{q=1}^3 \sum_{j=1}^3 (A_{jq} D_j(A_{iq}))(\bar{\mu}_t),$$

where D_j denotes the partial derivative with respect to the j -th component.

$$\sum_{q=1}^3 \sum_{j=1}^3 (A_{jq} D_j(A_{iq}))(x) = \sum_{j=1}^3 (D_j A) A_{\cdot j}^*(x).$$

Let us compute $D_j A$ by using the fact that $D_j(x) = \mathbf{e}_j$, where \mathbf{e}_j is the j -th vector of the canonical basis.

$$\begin{aligned} D_j A(x) &= -\alpha(D_j x x^* + x D_j x^*) - L(D_j(x)) \\ &= -\alpha(\mathbf{e}_j x^* + x \mathbf{e}_j^*) - L(\mathbf{e}_j). \end{aligned}$$

Then, we get

$$\begin{aligned} \sum_{j=1}^3 (D_j A) A_{\cdot j}^*(x) &= \sum_{j=1}^3 \left(-\alpha(\mathbf{e}_j x^* + x \mathbf{e}_j^*) - L(\mathbf{e}_j) \right) (\alpha \mathbf{e}_j - \alpha x x_j - L(\mathbf{e}_j) x) \\ &= \sum_{j=1}^3 \alpha^2 (-x_j \mathbf{e}_j - x + x_j \mathbf{e}_j + x_j^2 x) + L(\mathbf{e}_j) L(\mathbf{e}_j) x \\ &= -2\alpha^2 x + \sum_{j=1}^3 (\mathbf{e}_j \cdot x) \mathbf{e}_j - (\mathbf{e}_j \cdot \mathbf{e}_j) x \\ &= -2(\alpha^2 + 1)x. \end{aligned}$$

Hence, the process $(\bar{\mu}_t)_t$ solves the following Itô SDE

$$d\bar{\mu}_t = (A(\bar{\mu}_t)b - \varepsilon^2(\alpha^2 + 1)\bar{\mu}_t)dt + \varepsilon A(\bar{\mu}_t)dW_t.$$

We easily check that $|\bar{\mu}_t| = 1$, as expected. From this equation, we compute

$$\begin{aligned} d(\bar{\mu}_t \cdot b) &= \left\{ \alpha \left(-(\bar{\mu}_t \cdot b)^2 + |b|^2 \right) - \varepsilon^2(\alpha^2 + 1)\bar{\mu}_t \cdot b \right\} dt \\ &\quad - \varepsilon \left(-L(\bar{\mu}_t)b + \alpha((\bar{\mu}_t \cdot b)\bar{\mu}_t - b) \right) \cdot dW_t. \end{aligned}$$

It is easy to check that

$$(d(\bar{\mu}_t \cdot b)) \Big|_{\bar{\mu}_t = b/|b|} = -\varepsilon^2(\alpha^2 + 1)|b| dt.$$

As $|\bar{\mu}_t| = 1$, the stochastic integral is a true martingale and we easily get

$$\begin{aligned} \mathbb{E}[\bar{\mu}_t \cdot b]' &= \alpha(|b|^2 - \mathbb{E}[(\bar{\mu}_t \cdot b)^2]) - \varepsilon^2(\alpha^2 + 1)\mathbb{E}[\bar{\mu}_t \cdot b] \\ \mathbb{E}[\bar{\mu}_t \cdot b] - \mathbb{E}[\bar{\mu}_0 \cdot b] e^{-\varepsilon^2(\alpha^2 + 1)t} &= e^{-\varepsilon^2(\alpha^2 + 1)t} \int_0^t \alpha(|b|^2 - \mathbb{E}[(\bar{\mu}_s \cdot b)^2]) e^{\varepsilon^2(\alpha^2 + 1)s} ds \\ \limsup_{t \rightarrow +\infty} \mathbb{E}[\bar{\mu}_t \cdot b] &= \frac{|b|^2 \alpha}{\varepsilon^2(\alpha^2 + 1)} - \liminf_{t \rightarrow +\infty} e^{-\varepsilon^2(\alpha^2 + 1)t} \int_0^t \alpha \mathbb{E}[(\bar{\mu}_s \cdot b)^2] e^{\varepsilon^2(\alpha^2 + 1)s} ds \\ \limsup_{t \rightarrow +\infty} \mathbb{E}[\bar{\mu}_t \cdot b] &\leq \frac{\alpha}{\varepsilon^2(\alpha^2 + 1)} \left(|b|^2 - \liminf_{t \rightarrow +\infty} \mathbb{E}[(\bar{\mu}_t \cdot b)^2] \right) \end{aligned}$$

where the last inequality comes from Lemma 12. This implies that b cannot be an equilibrium point of the stochastic system $(\bar{\mu}_t)_t$. Moreover, if $\bar{\mu}_t \cdot b$ were converging to some deterministic

value $l \in [-|b|, |b|]$, we would get $l = \frac{\alpha}{\varepsilon^2(\alpha^2+1)}(|b|^2 - l^2)$. The only physically acceptable solution would be $l = \frac{1}{2} \left(\sqrt{4|b|^2 + \frac{\varepsilon^4(\alpha^2+1)^2}{\alpha^2}} - \frac{\varepsilon^2(\alpha^2+1)}{\alpha} \right) < |b|$.

Relying on a Stratonovich rule for writing the perturbation does not enable us to get a stochastic system converging to the stable equilibrium of the deterministic ODE. Actually, we can even prove that the whole sphere but a small northern cap is positive recurrent.

Proposition 4. *For all $|b| > \delta > \frac{1}{2} \left(\sqrt{4|b|^2 + \frac{\varepsilon^4(\alpha^2+1)^2}{\alpha^2}} - \frac{\varepsilon^2(\alpha^2+1)}{\alpha} \right)$, the set $\{x \in \mathcal{S}(\mathbb{R}^3) : x \cdot b \leq \delta\}$ is positive recurrent. Moreover, if $\tau_\delta = \inf\{t > 0 : \bar{\mu}_t \cdot b \leq \delta\}$,*

$$\mathbb{P}(\tau_\delta > t \mid \bar{\mu}_0 \cdot b > \delta) = O(t^{-1}).$$

Proof. Since $(\bar{\mu}_t)_t$ is an homogeneous Markov process, it is sufficient to prove that $\mathbb{E}[\tau_\delta \mid \bar{\mu}_0 \cdot b > \delta] < +\infty$. Assume $\bar{\mu}_0 \cdot b > \delta$. Using Doob's stopping time theorem, we can write

$$\begin{aligned} \bar{\mu}_{t \wedge \tau_\delta} \cdot b - \bar{\mu}_0 \cdot b &= \int_0^{t \wedge \tau_\delta} - \left\{ \alpha \left((\bar{\mu}_s \cdot b)^2 - |b|^2 \right) + \varepsilon^2(\alpha^2 + 1) \bar{\mu}_s \cdot b \right\} ds \\ &\quad - \int_0^{t \wedge \tau_\delta} \varepsilon \left(-L(\bar{\mu}_s)b + \alpha((\bar{\mu}_s \cdot b)\bar{\mu}_s - b) \right) \cdot dW_s. \\ \mathbb{E}[\bar{\mu}_{t \wedge \tau_\delta} \cdot b] - \mathbb{E}[\bar{\mu}_0 \cdot b] &= \int_0^t \mathbb{E} \left[\mathbf{1}_{\{s \leq \tau_\delta\}} \left\{ \alpha \left(-(\bar{\mu}_s \cdot b)^2 + |b|^2 \right) - \varepsilon^2(\alpha^2 + 1) \bar{\mu}_s \cdot b \right\} \right] ds \end{aligned}$$

For $s \leq \tau_\delta$, $\bar{\mu}_s \cdot b > \delta$. Hence,

$$\delta - \mathbb{E}[\bar{\mu}_0 \cdot b] \leq \mathbb{E}[\bar{\mu}_{t \wedge \tau_\delta} \cdot b] - \mathbb{E}[\bar{\mu}_0 \cdot b] \leq \mathbb{E}[t \wedge \tau_\delta] \left\{ \alpha \left(-\delta^2 + |b|^2 \right) - \varepsilon^2(\alpha^2 + 1)\delta \right\} \quad (2.8)$$

For $\delta > \frac{1}{2} \left(\sqrt{4|b|^2 + \frac{\varepsilon^4(\alpha^2+1)^2}{\alpha^2}} - \frac{\varepsilon^2(\alpha^2+1)}{\alpha} \right)$, the term $\left\{ \alpha \left(-\delta^2 + |b|^2 \right) - \varepsilon^2(\alpha^2 + 1)\delta \right\} < 0$. If we let t go to infinity in Equation (2.8), we deduce that $\lim_{t \rightarrow +\infty} \mathbb{E}[t \wedge \tau_\delta] < +\infty$. Using the monotone convergence theorem, we obtain that $\mathbb{E}[\lim_{t \rightarrow +\infty} t \wedge \tau_\delta] = \lim_{t \rightarrow +\infty} \mathbb{E}[t \wedge \tau_\delta] < +\infty$. Hence,

$$\lim_{t \rightarrow +\infty} \mathbb{E}[\tau_\delta \mathbf{1}_{\{\tau_\delta < t\}}] + t\mathbb{P}(\tau_\delta > t) < +\infty \quad (2.9)$$

Moreover $\lim_{t \rightarrow +\infty} \mathbb{E}[\tau_\delta \mathbf{1}_{\{\tau_\delta < t\}}] = \mathbb{E}[\tau_\delta \mathbf{1}_{\{\tau_\delta < +\infty\}}]$ and $\lim_{t \rightarrow +\infty} \mathbb{P}(\tau_\delta > t) = \mathbb{P}(\tau_\delta = +\infty)$. This implies that $\mathbb{P}(\tau_\delta < +\infty) = 1$. If we plug this result back into Equation (2.9), we also deduce that $\mathbb{E}[\tau_\delta] < +\infty$. \blacksquare

The physical phenomena modelled by the Itô and the Stratonovich rules.

Whereas, these two kinds of stochastic perturbations both model thermal effects, these are of completely different natures. As the time homogeneous dynamics obtained from the Stratonovich rule suggests it, the physical environment does not evolve with time, meaning that the temperature remains constant over time. Hence, the Stratonovich approach is well suited to model a constant injection of heat into the system.

On the contrary, the Itô approach describes the evolution of a model starting with a fixed amount of heat with no more heat injection after time 0. This slow decrease of the system temperature over time explains why we came up with an SDE with time decreasing coefficients.

3 Main results: long time behaviour

3.1 Almost sure convergence

In this part, we prove the almost sure convergence of μ_t to $b/|b|$ when t goes to infinity. This is achieved by studying the pathwise behaviour of the process $(\mu_t \cdot b)_t$.

Theorem 5. $\lim_{t \rightarrow \infty} \mu_t \cdot b = |b|$ *a.s.*

To prove this result, we need a preliminary result stating that the stochastic integral in Equation (2.4) actually vanishes at infinity.

Lemma 6.

$$\sup_t \int_0^t \frac{1}{h(u)} (-\mu_u \wedge b + \alpha((\mu_u \cdot b)\mu_u - b)) \cdot dW_u < \infty \quad a.s.$$

Proof of Theorem 5. From Lemma 6, we know that

$$\sup_t \int_0^t \frac{1}{h(u)} (-\mu_u \wedge b + \alpha((\mu_u \cdot b)\mu_u - b)) \cdot dW_u < \infty \quad a.s.$$

Hence, we can define for all $t \geq 0$

$$X_t = \mu_t \cdot b - \int_t^\infty \frac{\varepsilon}{h(u)} (-\mu_u \wedge b + \alpha((\mu_u \cdot b)\mu_u - b)) \cdot dW_u$$

Let $|b| > \delta > 0$ be chosen close to 0. There exists T such that for all $t \geq T$, $|X_t - \mu_t \cdot b| \leq \delta$. Moreover from Equation (2.4), we can deduce that for all $t > s > T$

$$X_t - X_s = \int_s^t -\mu_u \cdot b \frac{h'(u)}{h(u)} - \frac{\alpha}{h(u)} ((\mu_u \cdot b)^2 - |b|^2) du. \quad (3.1)$$

Let $\eta < |b|$ be chosen close to $|b|$. On the set $\{0 < \mu_u \cdot b < \eta\}$ we have $|\mu_u \wedge b|^2 \geq |b|^2 - \eta^2$. Thus,

$$-(\mu_u \cdot b) \frac{h'(u)}{h(u)} + \frac{\alpha}{h(u)} |\mu_u \wedge b|^2 \geq -|b| \frac{h'(u)}{h(u)} + \alpha \frac{|b|^2 - \eta^2}{h(u)}.$$

We can always choose T such that for all $u > T$,

$$-|b| \frac{h'(u)}{h(u)} + \alpha \frac{|b|^2 - \eta^2}{h(u)} \geq \alpha \frac{|b|^2 - \eta^2}{2h(u)}.$$

Hence, on the set $\{0 < \mu_u \cdot b < \eta\}$,

$$-(\mu_u \cdot b) \frac{h'(u)}{h(u)} + \frac{\alpha}{h(u)} |\mu_u \wedge b|^2 \geq \alpha \frac{|b|^2 - \eta^2}{2h(u)}. \quad (3.2)$$

On the set $\{\mu_u \cdot b \leq 0\}$ we have

$$\begin{aligned} -(\mu_u \cdot b) \frac{h'(u)}{h(u)} + \frac{\alpha}{h(u)} |\mu_u \wedge b|^2 &\geq (-\mu_u \cdot b) + \alpha |\mu_u \wedge b|^2 \frac{h'(u)}{h(u)} \\ &\geq \min(|b|, \alpha |b|^2) \frac{1}{2} \frac{h'(u)}{h(u)}. \end{aligned} \quad (3.3)$$

The last inequality comes from the fact that if $\pi/2 \leq x \leq 3\pi/2$, we have either $-\cos(x) \geq \sqrt{2}/2$ or $|\sin(x)| \geq \sqrt{2}/2$.

Therefore, by combining Equations (3.2) and (3.3), we find that there exists $\bar{T} \geq T$, such that for all $t \geq \bar{T}$, on the event $\{\mu_t \cdot b < \eta\}$ we have $-(\mu_t \cdot b) \frac{h'(t)}{h(t)} + \frac{\alpha}{h(t)} |\mu_t \wedge b|^2 \geq c \frac{h'(t)}{h(t)}$ where c is a positive real constant depending on η . Therefore, we deduce from Equation (3.1)

$$\begin{aligned} X_t - X_s &\geq -|b| \int_s^t \frac{h'(u)}{h(u)} \mathbf{1}_{\{\mu_u \cdot b > \eta\}} du + c \int_s^t \frac{h'(u)}{h(u)} \mathbf{1}_{\{\mu_u \cdot b \leq \eta\}} du \\ &\geq -|b| \int_s^t \frac{h'(u)}{h(u)} \mathbf{1}_{\{X_u > \eta - \delta\}} du + c \int_s^t \frac{h'(u)}{h(u)} \mathbf{1}_{\{X_u \leq \eta - \delta\}} du. \end{aligned}$$

The values of δ and η can always be chosen that $0 < \eta - 2\delta < |b|$.

Assume that $X_s \leq \eta - 2\delta$. Then, for all $t \geq s$ such that for all $u \in [s, t]$, $X_u \leq \eta - \delta$, we have

$$X_t - X_s \geq c \int_s^t \frac{h'(u)}{h(u)} du$$

As h'/h is not integrable, t must be finite, which means there exists $t \geq s$ such that $X_t > \eta - \delta > \eta - 2\delta$. Hence, we can assume that $X_s > \eta - 2\delta$.

Either, for all $t \geq s$, $X_t > \eta - 2\delta$, or thanks to the continuity of X there exists t_0 for which $X_{t_0} = \eta - 2\delta$ and we have just seen that, in this case, there exists $t \geq t_0$ such that $X_t \geq \eta - \delta$ and for all $u \in [t_0, t]$ $\eta - \delta \geq X_u > \eta - 2\delta$. This reasoning enables us to prove that for all $t \geq s$, $X_t \geq \eta - 2\delta$, ie. $\mu_t \cdot b \geq \eta - 3\delta$. As η can be chosen arbitrarily close to $|b|$ and δ arbitrarily small, this proves the almost sure convergence of $\mu_t \cdot b$ to $|b|$. ■

Proof of Lemma 6. From Doob's inequality we have

$$\begin{aligned} \mathbb{E} \left[\sup_t \left| \int_0^t \frac{1}{h(u)} (-\mu_u \wedge b + \alpha((\mu_u \cdot b)\mu_u - b)) \cdot dW_u \right|^2 \right] &\leq \\ &\int_0^\infty \frac{1}{h(u)^2} \mathbb{E} \left[(|b|^2 - |\mu_u \cdot b|^2) \right] (1 + \alpha^2) du. \end{aligned} \quad (3.4)$$

Now, we will prove that the r.h.s is finite.

From Equation (2.4), we get after integrating and taking the expectation for all $t > 0$

$$\begin{aligned} \mathbb{E}[\mu_t \cdot b] - \mathbb{E}[\mu_0 \cdot b] &= - \int_0^t \mathbb{E}[\mu_u \cdot b] \frac{h'(u)}{h(u)} - \frac{\alpha}{h(u)} \mathbb{E}[(\mu_u \cdot b)^2 - |b|^2] du \\ \mathbb{E}[\mu_t \cdot b] h'(t) + \mathbb{E}[\mu_t \cdot b] h'(t) &= \alpha \mathbb{E}[|b|^2 - (\mu_t \cdot b)^2] \\ \mathbb{E}[\mu_t \cdot b] - \frac{h(s)}{h(t)} \mathbb{E}[\mu_0 \cdot b] &= \frac{\alpha}{h(t)} \int_0^t \mathbb{E}[|b|^2 - (\mu_u \cdot b)^2] du \end{aligned}$$

Hence, we deduce that

$$\sup_t \frac{1}{h(t)} \int_0^t \mathbb{E}[|b|^2 - (\mu_u \cdot b)^2] du < \frac{2|b|}{\alpha} = \kappa.$$

Let us consider the upper-bound in Equation (3.4) truncated to t and perform an integration by parts to obtain

$$\begin{aligned}
& \int_0^t \frac{1}{h(u)^2} \mathbb{E} [(|b|^2 - |\mu_u \cdot b|^2)] du \\
&= \left[\frac{1}{h(u)^2} \int_0^u \mathbb{E} [(|b|^2 - |\mu_v \cdot b|^2)] dv \right]_0^t + \int_0^t \frac{2h'(u)}{h(u)^3} \int_0^u \mathbb{E} [(|b|^2 - |\mu_v \cdot b|^2)] dv du \\
&\leq \kappa \frac{1}{h(t)} + 2\kappa \int_0^t \frac{h'(u)}{h(u)^2} du \\
&\leq \kappa \left(\frac{1}{h(t)} + 2 \left(\frac{1}{h(0)} - \frac{1}{h(t)} \right) \right) \leq \frac{2\kappa}{h(0)}
\end{aligned}$$

This proves that the r.h.s of Equation (3.4) is finite and ends the proof of Lemma 6. \blacksquare

3.2 Convergence rate

In this section, we are interested in the behaviour of $h(t)(|b| - \mu_t \cdot b)$. In particular, we establish the rate of decrease of the \mathbb{L}^1 norm of $|b| - \mu_t \cdot b$ to zero.

Theorem 7. $\lim_{t \rightarrow \infty} \mathbb{E}[h(t) | |b| - \mu_t \cdot b |] = \frac{\varepsilon^2(1 + \alpha^2)}{2\alpha}.$

To prove this Theorem, we need the following lemma.

Lemma 8. $\lim_{t \rightarrow +\infty} \mathbb{E} [h(t)(|b| - \mu_t \cdot b)^2] = 0.$

Proof of Lemma 8. We define the process X by $X_t = h(t)(|b| - \mu_t \cdot b)^2$ and apply Itô's formula to find

$$\begin{aligned}
dX_t &= h'(t)(|b| - \mu_t \cdot b)^2 dt + 2h(t)(|b| - \mu_t \cdot b)d(-\mu_t \cdot b) + h(t)d \langle \mu \cdot b \rangle_t \\
&= \frac{h'(t)}{h(t)} X_t dt + 2(|b| - \mu_t \cdot b) \left(h'(t)(\mu_t \cdot b) + \alpha(|b|^2 - (\mu_t \cdot b)^2) \right) dt \\
&\quad + 2\varepsilon(|b| - \mu_t \cdot b) (-\mu_t \wedge b + \alpha((\mu_t \cdot b)\mu_t - b)) dW_t + \frac{\varepsilon^2(\alpha^2 + 1)}{h(t)} (|b|^2 - (\mu_t \cdot b)^2) dt.
\end{aligned}$$

Then, we integrate and take expectation to obtain

$$\begin{aligned}
\mathbb{E}[X_t]' &= \frac{h'(t)}{h(t)} \mathbb{E}[X_t] + \mathbb{E} [2h'(t)(|b| - \mu_t \cdot b)(\mu_t \cdot b)] + 2\alpha \mathbb{E} [(|b| - \mu_t \cdot b)(|b|^2 - (\mu_t \cdot b)^2)] \\
&\quad + h'(t) \mathbb{E} [|b|^2 - (\mu_t \cdot b)^2] \\
&= -\frac{h'(t)}{h(t)} \mathbb{E}[X_t] + 2h'(t)|b| \mathbb{E}[|b| - \mu_t \cdot b] - 2\frac{\alpha}{h(t)} \mathbb{E} [(|b| + \mu_t \cdot b)X_t] + h'(t) \mathbb{E} [|b|^2 - (\mu_t \cdot b)^2] \\
&= -2\frac{\alpha}{\varepsilon^2(\alpha^2 + 1)} h'(t)|b| \mathbb{E}[X_t] - 2\frac{\alpha}{\varepsilon^2(\alpha^2 + 1)} h'(t) \mathbb{E}[X_t(\mu_t \cdot b)] - \frac{h'(t)}{h(t)} \mathbb{E}[X_t] \\
&\quad + h'(t) \mathbb{E} [(|b| - \mu_t \cdot b)(3|b| + \mu_t \cdot b)]
\end{aligned}$$

Let $\beta = 2|b|\frac{\alpha}{\varepsilon^2(\alpha^2+1)}$. We integrate the previous equation to find

$$\begin{aligned}\mathbb{E}[X_t] - \mathbb{E}[X_0] e^{-\beta(h(t)-h(0))} &= e^{-\beta h(t)} \int_0^t \left(-\frac{\beta}{|b|} h'(s) \mathbb{E}[X_s(\mu_s \cdot b)] - h'(s) \mathbb{E}[(|b| - \mu_s \cdot b)^2] \right. \\ &\quad \left. + h'(s) \mathbb{E}[(|b| - \mu_s \cdot b)(3|b| + \mu_s \cdot b)] \right) e^{\beta h(s)} ds \\ &= e^{-\beta h(t)} \int_0^t \left(-\frac{\beta}{|b|} h'(s) \mathbb{E}[X_s(\mu_s \cdot b)] - h'(s) \mathbb{E}[(|b| - \mu_s \cdot b)^2] \right. \\ &\quad \left. + h'(s) \mathbb{E}[(|b| - \mu_s \cdot b)(3|b| + \mu_s \cdot b)] \right) e^{\beta h(s)} ds.\end{aligned}$$

From Theorem 5 combined with the bounded convergence theorem, we know that $\mathbb{E}[(|b| - \mu_t \cdot b)^2]$ and $\mathbb{E}[(|b| - \mu_t \cdot b)(3|b| + \mu_t \cdot b)]$ tend to zero when t goes to infinity. Then, we can apply Lemma 11 to show that

$$e^{-\beta h(t)} \int_0^t h'(s) \left(-\mathbb{E}[(|b| - \mu_s \cdot b)^2] + \mathbb{E}[(|b| - \mu_s \cdot b)(3|b| + \mu_s \cdot b)] \right) e^{\beta h(s)} ds \xrightarrow{t \rightarrow +\infty} 0.$$

Hence, we get

$$\begin{aligned}\limsup_{t \rightarrow +\infty} \mathbb{E}[X_t] &= -\frac{\beta}{|b|} \liminf_{t \rightarrow +\infty} e^{-\beta h(t)} \int_{h(0)}^{h(t)} \mathbb{E}[X_{h^{-1}(v)}(\mu_{h^{-1}(v)} \cdot b)] e^{\beta v} dv \\ &\leq -\frac{\beta}{|b|} \liminf_{t \rightarrow +\infty} \mathbb{E}[X_t(\mu_t \cdot b)]\end{aligned}$$

where we have used Lemma 12 for the last inequality. Finally, Fatou's Lemma yields

$$\limsup_{t \rightarrow +\infty} \mathbb{E}[X_t] \leq -\frac{\beta}{|b|} \mathbb{E}[\liminf_{t \rightarrow +\infty} X_t(\mu_t \cdot b)] \leq -\beta \mathbb{E}[\liminf_{t \rightarrow +\infty} X_t] \leq 0.$$

Since, $X_t \geq 0$ a.s., we conclude that $\lim_{t \rightarrow +\infty} \mathbb{E}[X_t] = 0$. ■

Proof of Theorem 7. As $|b| - \mu_t \cdot b \geq 0$, the \mathbb{L}^1 norm boils down to a basic expectation. Let us define $\xi_t = |b| - \mu_t \cdot b$ for $t \geq 0$. From Equation (2.4), we get

$$\begin{aligned}d\xi_t &= -\xi_t \frac{h'(t)}{h(t)} dt + |b| \frac{h'(t)}{h(t)} dt + \frac{\alpha}{h(t)} \left((\mu_t \cdot b)^2 - |b|^2 \right) dt - \frac{\varepsilon}{h(t)} (-\mu_t \wedge b + \alpha((\mu_t \cdot b)\mu_t - b)) \cdot dW_t \\ &= -\xi_t \frac{h'(t)}{h(t)} dt + |b| \frac{h'(t)}{h(t)} dt - \frac{\alpha}{h(t)} \xi_t (2|b| - \xi_t) dt - \frac{\varepsilon}{h(t)} (-\mu_t \wedge b + \alpha((\mu_t \cdot b)\mu_t - b)) \cdot dW_t\end{aligned}$$

If we introduce $Z_t = h(t)(|b| - \mu_t \cdot b)$, we can write

$$dZ_t = (h'(t)|b| - \alpha\xi_t(2|b| - \xi_t)) dt - \varepsilon(-\mu_t \wedge b + \alpha((\mu_t \cdot b)\mu_t - b)) \cdot dW_t$$

From the dynamics of Y , we deduce that $\mathbb{E}[Z_t]$ solves the following differential equation

$$\begin{aligned}\mathbb{E}[Z_t]' &= |b| h'(t) - \alpha(2|b| \mathbb{E}[\xi_t] - \mathbb{E}[\xi_t^2]) \\ \mathbb{E}[Z_t]' &= |b| h'(t) - \alpha 2|b| \frac{\mathbb{E}[Z_t]}{h(t)} + \alpha \mathbb{E}[\xi_t^2] \\ \mathbb{E}[Z_t]' &= |b| h'(t) - \alpha \frac{2|b|}{\varepsilon^2(\alpha^2 + 1)} h'(t) \mathbb{E}[Z_t] + \alpha \mathbb{E}[\xi_t^2] \\ \left(\mathbb{E}[Z_t] e^{\int_0^t \frac{2\alpha|b|}{\varepsilon^2(\alpha^2 + 1)} h'(u) du} \right)' &= \left(|b| h'(t) + \alpha \mathbb{E}[\xi_t^2] \right) e^{\int_0^t \frac{2\alpha|b|}{\varepsilon^2(\alpha^2 + 1)} h'(u) du}\end{aligned}$$

Now, we can integrate the previous equation to obtain

$$\begin{aligned}\mathbb{E}[Z_t] e^{\frac{2\alpha|b|}{\varepsilon^2(\alpha^2 + 1)}(h(t) - h(0))} - \mathbb{E}[Z_0] &= |b| \int_0^t h'(u) e^{\frac{2\alpha|b|}{\varepsilon^2(\alpha^2 + 1)}(h(u) - h(0))} du \\ &\quad + \alpha \int_0^t \mathbb{E}[\xi_u^2] e^{\frac{2\alpha|b|}{\varepsilon^2(\alpha^2 + 1)}(h(u) - h(0))} du \\ \mathbb{E}[Z_t] - \mathbb{E}[Z_0] e^{-\frac{2\alpha|b|}{\varepsilon^2(\alpha^2 + 1)}(h(t) - h(0))} &= \frac{\varepsilon^2(\alpha^2 + 1)}{2\alpha} \left(1 - e^{-\frac{2\alpha|b|}{\varepsilon^2(\alpha^2 + 1)}(h(t) - h(0))} \right) \\ &\quad + \alpha e^{-\frac{2\alpha|b|}{\varepsilon^2(\alpha^2 + 1)}(h(t) - h(0))} \int_0^t \mathbb{E}[\xi_u^2] e^{\frac{2\alpha|b|}{\varepsilon^2(\alpha^2 + 1)}(h(u) - h(0))} du\end{aligned}$$

From Theorem 5, we know that ξ_t tends to 0 a.s., therefore the bounded convergence theorem yields that $\lim_{u \rightarrow \infty} \mathbb{E}[\xi_u^2] = 0$. Hence, as $h(t)$ tends to infinity with t , it is easy to show that

$$\lim_{t \rightarrow \infty} e^{-\frac{2\alpha|b|}{\varepsilon^2(\alpha^2 + 1)}(h(t) - h(0))} \int_0^t \mathbb{E}[\xi_u^2] e^{\frac{2\alpha|b|}{\varepsilon^2(\alpha^2 + 1)}(h(u) - h(0))} du = 0.$$

Then, we can deduce that

$$\lim_{t \rightarrow \infty} \mathbb{E}[Z_t] = \frac{\varepsilon^2(\alpha^2 + 1)}{2\alpha}.$$

■

As a corollary of Theorem 7, we can prove the following results using Markov's inequality.

Corollary 9. *For all $0 < \beta < 1/2$ and $\eta > 0$, $\mathbb{P}(t^\beta(|b| - \mu_t \cdot b) \geq \eta) \rightarrow 0$.*

4 Hysteresis phenomena

In this section, we want to study the impact of the stochastic perturbation on the reversibility of the system; we are wondering whether the stochastic part may induce an hysteresis phenomenon. In order to observe this, the particle is submitted to an external field linearly varying from $+\mathbf{b}$ to $-\mathbf{b}$ where $\mathbf{b} \in \mathcal{S}(\mathbb{R}^3)$ and with constant direction and bounded modulus. We have seen in Section 3 that when the external field is fixed, the magnetic moment μ asymptotically stabilizes along this field. If the external field varies sufficiently slowly compared to the stabilization rate of μ , we expect that μ will take different back and forth paths when the external field switches from $+\mathbf{b}$ to $-\mathbf{b}$ and then from $-\mathbf{b}$ to $+\mathbf{b}$: this characterizes the hysteretic behaviour of the system.

In order to highlight this property, we will study the evolution of a suitably rescaled system on the time interval $[0, 1]$ and show that the average back and forth paths of $\mu_t \cdot b$ can not cross at the point $t = 1/2$.

We consider a two time scale model: a slower scale for the variations of the external field and a faster scale for the Landau Lifshitz evolution of the magnetic moment.

Let $\eta > 0$ be a fixed time scale and $\mathbf{b} \in \mathcal{S}(\mathbb{R}^3)$ the direction of the external field. We define the external field b^η linearly varying between $+\mathbf{b}$ and $-\mathbf{b}$ on the interval $[0, 1/\eta]$ by

$$b^\eta(t) = (1 - 2t\eta) \mathbf{b} \quad \text{for } t \in [0, 1/\eta]$$

We assume that the magnetic moment μ^η is affected by $b^\eta(t)$ according to the following equation for $t \in [0, 1/\eta]$

$$\begin{cases} dY_t^\eta &= -\mu_t^\eta \wedge (b^\eta(t) dt + \varepsilon dW_t) - \alpha \mu_t^\eta \wedge \mu_t^\eta \wedge (b^\eta(t) dt + \varepsilon dW_t) \\ \mu_t^\eta &= \frac{Y_t^\eta}{|Y_t^\eta|} \\ Y_0^\eta &= \mathbf{b} \end{cases}$$

In order to work on the interval $[0, 1]$, we introduce rescaled versions of both the external field and the magnetic moment defined for $t \in [0, 1]$.

$$b(t) = b^\eta(t/\eta), \quad Z_t^\eta = Y_{t/\eta}^\eta, \quad \lambda_t^\eta = \mu_{t/\eta}^\eta.$$

Using the time scale property of the stochastic integral, we can write

$$dZ_t^\eta = -\lambda_t^\eta \wedge \left(b(t) \frac{1}{\eta} dt + \varepsilon dW_{t/\eta} \right) - \alpha \lambda_t^\eta \wedge \lambda_t^\eta \wedge \left(b(t) \frac{1}{\eta} dt + \varepsilon dW_{t/\eta} \right)$$

From the scaling property of the Brownian motion, we know that $(\sqrt{\eta} W_{t/\eta})$ is still a Brownian motion. So we get

$$dZ_t^\eta = -\lambda_t^\eta \wedge \left(b(t) \frac{1}{\eta} dt + \varepsilon \frac{1}{\sqrt{\eta}} dW_t \right) - \alpha \lambda_t^\eta \wedge \lambda_t^\eta \wedge \left(b(t) \frac{1}{\eta} dt + \varepsilon \frac{1}{\sqrt{\eta}} dW_t \right)$$

It is important to notice that the factor η acts as a time scale parameter for the deterministic part, but that the corresponding scaling parameter for the stochastic part is $\sqrt{\eta}$.

Following the proof of Proposition 1, it is obvious to show that $d|Z_t^\eta|^2 = 2(1 + \alpha^2)\varepsilon^2/\eta dt$. Then, we introduce for $t \in [0, 1]$

$$h^\eta(t) = |Z_t^\eta| = \sqrt{2(1 + \alpha^2)\varepsilon^2 t/\eta + 1}.$$

The Ito formula applied to $(\lambda_t^\eta \cdot \mathbf{b})_t$ yields

$$\begin{aligned} d(\lambda_t^\eta \cdot \mathbf{b}) &= -(\lambda_t^\eta \cdot \mathbf{b}) \frac{h^{\eta'}(t)}{h^\eta(t)} dt + \alpha \frac{1 - 2t}{\eta h^\eta(t)} |\lambda_t^\eta \wedge \mathbf{b}|^2 dt \\ &\quad - \frac{\varepsilon}{\sqrt{\eta} h^\eta(t)} ((\lambda_t^\eta \wedge dW_t) \cdot \mathbf{b} + \alpha(\lambda_t^\eta \cdot \mathbf{b})(\lambda_t^\eta \cdot dW_t) - \alpha(\mathbf{b} \cdot dW_t)) \end{aligned}$$

The stochastic part vanishes when taking expectation as in the previous section to find

$$\mathbb{E}(\lambda_t^\eta \cdot \mathbf{b}) - \lambda_0 \cdot \mathbf{b} = \int_0^t -\mathbb{E}(\lambda_u^\eta \cdot \mathbf{b}) \frac{h^{\eta'}(u)}{h^\eta(u)} du + \alpha \frac{1 - 2u}{\eta h^\eta(u)} \mathbb{E}|\lambda_u^\eta \wedge \mathbf{b}|^2 du \quad (4.1)$$

Proposition 10. For all $t \in [0, 1/2]$,

$$\mathbb{E}(\lambda_t^\eta \cdot \mathbf{b}) \geq \frac{1}{h^\eta(t)} \geq \frac{1}{\sqrt{1 + \frac{(1+\alpha^2)\varepsilon^2}{\eta}}}.$$

Proof. Since the process λ^η is pathwise continuous and bounded, it is easy to show that the deterministic function $e(t) : t \mapsto \mathbb{E}(\lambda_t^\eta \cdot \mathbf{b})$ is of class C^1 . Hence, we can differentiate Equation (4.1)

$$e'(t) = -e(t) \frac{h^{\eta'}(t)}{h^\eta(t)} + \alpha \frac{1-2t}{\eta h^\eta(t)} \mathbb{E} |\lambda_t^\eta \wedge \mathbf{b}|^2$$

As $t \leq 1/2$, the second term on the r.h.s is non-negative, hence

$$e'(t) \geq -e(t) \frac{h^{\eta'}(t)}{h^\eta(t)}$$

From this inequality, we deduce that $(e(t)h^\eta(t))' \geq 0$, which leads to the following lower bound

$$e(t) \geq \frac{1}{h^\eta(t)} \quad \text{for } t \leq 1/2$$

■

5 Numerical experiments

In this section, we want to illustrate the theoretical results obtained in Sections 3 and 4 using some numerical simulations.

Long time behaviour. We consider the stochastic system (2.1) and discretize it with the help of an Euler scheme $(\bar{Y}, \bar{\mu})$, on a time grid with step size $\delta t > 0$.

Figure 1 shows the long time behaviour of $(\bar{\mu}_t \cdot \mathbf{b})_{t \geq 0}$, for one path of the scheme $(\bar{Y}, \bar{\mu})$, with time step size $\delta t = 0.01$ and for different values of the damping parameter α . The parameter ε is fixed to 0.1, we have taken $|\mathbf{b}| = 1$, and set $\mu_0 = -\mathbf{b}$. The almost sure convergence of $\mu_t \cdot \mathbf{b}$ to $|\mathbf{b}|$, as stated by Theorem 5, is well illustrated by Figure 1 and one can also see how the parameter α impacts the characteristic time of the system, ie. the time needed to stabilize around the limit.

Now, we wish to compare the rates of convergence studied in Subsection 3.2 to numerical observations. From Theorem 7, $\frac{2\alpha\sqrt{2}}{\varepsilon\sqrt{1+\alpha^2}}\sqrt{t} \mathbb{E}(|\mathbf{b}| - \mu_t \cdot \mathbf{b})$ converges to 1 when t goes to infinity. This is illustrated by Figure 2 for different values of α . This figure confirms that decreasing the parameter α leads to a decrease of the convergence rate of $\mathbb{E}(|\mathbf{b}| - \mu_t \cdot \mathbf{b})$.

Hysteresis phenomena. On Figure 3, we can observe a typical pathwise hysteresis phenomenon, which not only illustrates Proposition 10 but also suggests that the result of this Proposition could be well improved by proving a almost sure lower bound (probably for sufficiently small values η). On Figure 3, the forward path (red curve) is almost stuck to the value 1 on the interval $[0, 1]$, we could then be tempted to think that the lower bound of Proposition 10 lacks some accuracy.

Figure 1: Almost sure convergence of $\mu_t \cdot b$ with $\mu_0 = -b$, $|b| = 1$, $\varepsilon = 0.1$.

On the contrary, when η becomes small, which corresponds to a slower scale for the variations of the external field, Figures 4 and 5 show a very sharp revolving around $t = 1/2$. The evolution of $\mathbb{E}\lambda_t^\eta \cdot b$ is very steep in the neighborhood of $1/2$, which corresponds to a change of sign of $b(t)$. By closely looking at Figure 5, we notice that the lower bound $1/h^\eta(t)$ is crossed for t slightly larger than $1/2$. This phenomenon will be all the more pronounced as η goes to zero. In that sense, the lower bound $1/h^\eta(t)$ becomes nearly optimal for t lower but close to $1/2$.

6 Conclusion

In this article, we analyzed the long time behaviour of the SDE modeling the evolution of a magnet submitted to a perturbed external field. The rate of convergence of the magnetic moment is particularly interesting and holds for any dissipation coefficient $\alpha > 0$. This result has been obtained by combining the ODE technique with Itô's formula. The second result concerns the hysteresis behaviour of the system induced by the stochastic perturbation. These two results illustrate the dissipative effects of a stochastic perturbation on a ferromagnet by giving a first glimpse on how thermal effects can be modeled in the framework of micromagnetism.

Figure 2: Convergence of $\frac{2\alpha\sqrt{2}}{\varepsilon\sqrt{1+\alpha^2}}\sqrt{t} \mathbb{E}(|b| - \mu_t.b)$ with $\mu_0 = -b$, $|b| = 1$ and $\varepsilon = 0.1$. The horizontal dashed line is at level one. The expectation is computed using a Monte-Carlo method with 100 samples.

Figure 3: Pathwise hysteresis phenomena with $\alpha = 1$, $\varepsilon = 0.005$ and $\eta = 0.01$. The red curve is the forward path whereas the blue curve is the backward path. The x -axis is time.

Figure 4: Pathwise hysteresis phenomena with $\alpha = 1$, $\varepsilon = 0.01$ and $\eta = 3.1E - 5$. The blue curve is the evolution of $\mu_t \cdot \mathbf{b}$ and the green curve is $1/h^\eta(t)$. The x -axis is time.

Figure 5: Zoom of Figure 4 around $t = 1/2$. The blue curve is the evolution of $\mu_t \cdot \mathbf{b}$ and the green curve is $1/h^\eta(t)$.

Lemma 11. Let $a > 0$ and f be a continuous function such that $\lim_{t \rightarrow +\infty} h(t)f(t) = 0$. Then, $e^{-ah(t)} \int_0^t f(u) e^{ah(u)} du \xrightarrow{t \rightarrow +\infty} 0$.

Proof. The function h is a one to one map from $[0, +\infty)$ to $[h(0), +\infty)$. Hence, a change of variable yields

$$\int_0^t f(u) e^{ah(u)} du = \int_{h(0)}^{h(t)} \frac{f(h^{-1}(v))}{h'(h^{-1}(v))} e^{av} dv.$$

Remember that $h'(s) = \frac{\varepsilon^2(\alpha^2+1)}{h(s)}$. Hence, as the function h^{-1} is increasing, we deduce that $\frac{f(h^{-1}(v))}{h'(h^{-1}(v))} \xrightarrow{v \rightarrow +\infty} 0$. Then, it is easy to show the result. \blacksquare

Lemma 12. Let $a > 0$ and f be a continuous function. Then,

$$\liminf_{t \rightarrow +\infty} e^{-at} \int_0^t f(u) e^{au} du \geq \frac{1}{a} \liminf_{t \rightarrow +\infty} f(t).$$

Proof. We define $l = \liminf_{t \rightarrow +\infty} f(t)$. Let $\eta > 0$, there exists $T > 0$, such that for all $t \geq T$, $f(t) \geq l - \eta$.

$$\begin{aligned} e^{-at} \int_0^t f(u) e^{au} du &= e^{-at} \int_0^T f(u) e^{au} du + e^{-at} \int_T^t f(u) e^{au} du \\ &\geq e^{-at} \int_0^T f(u) e^{au} du + e^{-at} \int_T^t (l - \eta) e^{au} du \\ \liminf_{t \rightarrow +\infty} e^{-at} \int_0^t f(u) e^{au} du &\leq \frac{l - \eta}{a}. \end{aligned}$$

As the inequality holds for all η , the result easily follows. \blacksquare
